1. HOMEWORK 1 (DUE: SEP 21)

Problem 1.1. Let \mathcal{L} be a positive-definite linear functional with monic OPS $\{P_n(x)\}_{n \geq 0}$. Prove the following extremal property: for any monic real polynomial $\pi(x) \neq P_n(x)$ of degree n ,

$$\mathcal{L}(P_n(x)^2) < \mathcal{L}(\pi(x)^2).$$

Solution. Let $\pi(x) = \sum_{k=0}^n a_k P_k(x)$. Since both $\pi(x)$ and $P_n(x)$ are monic, we have $a_n = 1$ [3 points]. Then

$$\begin{aligned} \mathcal{L}(\pi(x)^2) &= \sum_{k=0}^n a_k^2 \mathcal{L}(P_k(x)^2) \quad [4 \text{ points}] \\ &\geq a_n^2 \mathcal{L}(P_n(x)^2) = \mathcal{L}(P_n(x)^2) \quad [3 \text{ points}]. \end{aligned}$$

□

Problem 1.2. Let \mathcal{L} be a linear functional such that $\Delta_n \neq 0$ for all $n \geq 0$. Prove that if $\pi(x)$ is a polynomial such that $\mathcal{L}(x^k \pi(x)) = 0$ for all $k \geq 0$, then $\pi(x) = 0$.

Solution. Since $\Delta_n \neq 0$, there is a monic OPS $\{P_n(x)\}_{n \geq 0}$ for \mathcal{L} [3 points]. Let $\pi(x) = \sum_{k=0}^n a_k P_k(x)$. Since $\mathcal{L}(x^k \pi(x)) = 0$ for all $k \geq 0$, we have $\mathcal{L}(p(x) \pi(x)) = 0$ for any polynomial $p(x)$ [3 points]. Then, for each $0 \leq k \leq n$, we have $0 = \mathcal{L}(P_k(x) \pi(x)) = a_k \mathcal{L}(P_k(x)^2)$ [2 points]. Since $\mathcal{L}(P_k(x)^2) \neq 0$, we get $a_k = 0$ for all $0 \leq k \leq n$ [2 points]. Hence $\pi(x) = 0$.

A common mistake: It is not true in general that $\mathcal{L}(x^k P_n(x)) = 0$ for $k \neq n$. We can only say that $\mathcal{L}(x^k P_n(x)) = 0$ for $k < n$. □

Problem 1.3. The *Tchebyshev polynomials of the second kind* $U_n(x)$ are defined by

$$U_n(x) = \frac{\sin(n+1)\theta}{\sin \theta}, \quad x = \cos \theta, \quad n \geq 0.$$

- (1) Prove that $U_n(x)$ is a polynomial of degree n .
- (2) Prove that

$$U_{n+1}(x) = 2xU_n(x) - U_{n-1}(x), \quad n \geq 0,$$

where $U_{-1}(x) = 0$ and $U_0(x) = 1$.

- (3) Prove that

$$\int_{-1}^1 U_m(x) U_n(x) (1-x^2)^{1/2} dx = \frac{\pi}{2} \delta_{m,n}.$$

- (4) Find the 3-term recurrence for the normalized Tchebyshev polynomials of the second kind. More precisely, find the numbers b_n and λ_n such that

$$\hat{U}_{n+1}(x) = (x - b_n) \hat{U}_n(x) - \lambda_n \hat{U}_{n-1}(x), \quad n \geq 0,$$

where $\hat{U}_n(x)$ is the monic polynomial that is a scalar multiple of $U_n(x)$.

Solution. (1) This follows from (2) [2 points].

- (2) By the addition rule for the sine function,

$$\begin{aligned} \sin(n+1)\theta &= \sin n\theta \cos \theta + \cos n\theta \sin \theta, \\ \sin(n-1)\theta &= \sin n\theta \cos \theta - \cos n\theta \sin \theta. \end{aligned}$$

Adding the two equations and dividing both sides by $\sin \theta$, we get

$$U_n(x) + U_{n-2}(x) = 2xU_{n-1}(x), \quad n \geq 1 \quad [2 \text{ points}].$$

This is equivalent to the recurrence in the problem.

(3) By the change of variables $x = \cos \theta$, $0 \leq \theta \leq \pi$, with $dx = -\sin \theta d\theta = -\sqrt{1-x^2}d\theta$,

$$\begin{aligned} & \int_{-1}^1 U_m(x)U_n(x)(1-x^2)^{1/2}dx \\ &= \int_0^\pi \sin(m+1)\theta \sin(n+1)\theta d\theta \quad [2 \text{ points}] \\ &= \frac{1}{2} \int_0^\pi (\cos(m-n)\theta + \cos(m+n)\theta) d\theta \quad [2 \text{ points}] \\ &= \frac{\pi}{2} \delta_{m,n}. \end{aligned}$$

(4) Since $\deg U_n(x) = 2^n$ for all $n \geq 0$, we have $\hat{U}_n(x) = 2^{-n}U_n(x)$. Dividing both sides of the recurrence in (2) by 2^{n+1} , we obtain $b_n = 0$ and $\lambda_n = 1/4$ [2 points]. \square

Problem 1.4. Let $\{P_n(x)\}_{n \geq 0}$ be the monic OPS for a linear functional \mathcal{L} with three-term recurrence

$$P_{n+1}(x) = (x - b_n)P_n(x) - \lambda_n P_{n-1}(x), \quad n \geq 0.$$

(1) Prove that

$$P_n(x) = \begin{vmatrix} x - b_0 & 1 & & 0 \\ \lambda_1 & x - b_1 & \ddots & \\ & \ddots & \ddots & 1 \\ 0 & & \lambda_{n-1} & x - b_{n-1} \end{vmatrix}.$$

(2) Prove that

$$P_n(x) = \begin{vmatrix} x - b_0 & \sqrt{\lambda_1} & & 0 \\ \sqrt{\lambda_1} & x - b_1 & \ddots & \\ & \ddots & \ddots & \sqrt{\lambda_{n-1}} \\ 0 & & \sqrt{\lambda_{n-1}} & x - b_{n-1} \end{vmatrix}.$$

(3) Using (2) prove that if $b_n \in \mathbb{R}$ and $\lambda_n > 0$ for all, then $P_n(x)$ has real roots only.

Solution. (1) Let $Q_n(x)$ be the determinant on the right-hand side. Expanding the determinant along the last row, we obtain the recursion

$$Q_n(x) = (x - b_{n-1})Q_{n-1}(x) - \lambda_{n-1}Q_{n-2}(x) \quad [2 \text{ points}].$$

Since $P_n(x)$ and $Q_n(x)$ satisfy the same recurrence with the initial conditions $Q_0(x) = 1$ and $Q_1(x) = x - b_0$, we obtain that $Q_n(x) = P_n(x)$.

(2) Let $A_n = (\alpha_{i,j})$ be the matrix in (1) and let B_n be the matrix in (2). Then it suffices to find an invertible diagonal matrix $D = \text{diag}(d_i)$ such that $B_n = DA_nD^{-1}$ [3 points]. To do this, observe that $DA_nD^{-1} = (d_i\alpha_{i,j}d_j^{-1})$. Since B_n and DA_nD^{-1} are tri-diagonal matrices, we have $B_n = DA_nD^{-1}$ if and only if the following hold:

$$(1.1) \quad \beta_{i,i} = d_i\alpha_{i,i}d_i^{-1},$$

$$(1.2) \quad \beta_{i,i+1} = d_i\alpha_{i,i+1}d_{i+1}^{-1},$$

$$(1.3) \quad \beta_{i+1,i} = d_{i+1}\alpha_{i+1,i}d_i^{-1}.$$

Since $\alpha_{i,i+1} = 1$ and $\beta_{i,i+1} = \sqrt{\lambda_{i+1}}$, (1.2) is equivalent to $d_{i+1} = d_i/\sqrt{\lambda_{i+1}}$. Indeed, if we set $d_0 = 1$ and $d_{i+1} = d_i/\sqrt{\lambda_{i+1}}$, then all three conditions above hold [3 points].

Note: Alternatively, it can be proved directly that the right-hand side of the equation satisfies the same recurrence as $P_n(x)$.

(3) Since the zeros of $P_n(x)$ are the eigenvalues of a real symmetric matrix, they are real [2 points]. \square

2. HOMEWORK 2 (DUE: OCT 5)

Problem 2.1. Let id be the identity permutation.

- (1) Find the number of permutations $\pi \in \mathfrak{S}_6$ such that $\pi^2 = id$.
- (2) Find the number of permutations $\pi \in \mathfrak{S}_6$ such that $\pi^3 = id$.
- (3) Find the number of permutations $\pi \in \mathfrak{S}_6$ such that $\pi^4 = id$.
- (4) Find the number of permutations $\pi \in \mathfrak{S}_6$ such that $\pi^5 = id$.
- (5) Find the number of permutations $\pi \in \mathfrak{S}_6$ such that $\pi^6 = id$.

Solution. We have $\pi^k = id$ if and only if every cycle of π is of length divisible by k . For example, if $\pi^6 = id$, then the decreasing sequence of the lengths of cycles of π must be (6) , $(3, 3)$, $(3, 2, 1)$, $(3, 1, 1, 1)$, $(2, 2, 2)$, $(2, 2, 1, 1)$, $(2, 1, 1, 1, 1)$, $(1, 1, 1, 1, 1, 1)$. The number of such permutations is $5!$, $\binom{6}{3} \frac{1}{2} 2^2$, $\binom{6}{3} \binom{3}{2} \cdot 2$, $\binom{6}{3} \cdot 2$, $5 \cdot 3$, $\binom{6}{4} \cdot 3$, $\binom{6}{2}$, 1 , respectively. In this way we get the answers as follows.

- (1) 76 [2 points]
- (2) 81 [2 points]
- (3) 256 [2 points]
- (4) 145 [2 points]
- (5) 396 [2 points]

□

Problem 2.2. Let c_1, \dots, c_n be a sequence of nonnegative integers such that $\sum_{i=1}^n i c_i = n$. Show that the number of permutations $\pi \in \mathfrak{S}_n$ with c_i cycles of length i for all $i = 1, \dots, n$ is

$$\frac{n!}{\prod_{i=1}^n i^{c_i} c_i!}.$$

Solution. Let X be the set of such permutations. We construct a map $\phi : \mathfrak{S}_n \rightarrow X$ as follows. Given $\sigma = \sigma_1 \cdots \sigma_n \in \mathfrak{S}_n$, let $\phi(\sigma)$ be the permutation whose cycle notation is obtained from the word $\sigma_1 \cdots \sigma_n$ by placing parentheses so that the first c_1 cycles are of length 1, the next c_2 cycles are of length 2, and so on [3 points]. By the construction, this gives a map $\phi : \mathfrak{S}_n \rightarrow X$.

For any $\pi \in X$, there are $c_i!$ ways to arrange its c_i cycles and i ways to cyclically shift each each of these cycles. Therefore, there are $\prod_{i=1}^n i^{c_i} c_i!$ permutations $\sigma \in \mathfrak{S}_n$ whose image under ϕ is π [4 points]. This shows that $|X| = |\mathfrak{S}_n| / \prod_{i=1}^n i^{c_i} c_i!$ as desired [3 points]. □

Problem 2.3. For $\pi \in \mathfrak{S}_n$, let $\ell(\pi)$ be the smallest number of simple transpositions whose product is π . Prove that $\ell(\pi) = \text{inv}(\pi)$.

Solution. Suppose that $\pi = s_1 \cdots s_r$ for some simple transpositions s_i 's. Since multiplying a simple transposition increases or decreases the number of inversions by 1, we have $r \geq \text{inv}(\pi)$ [3 points]. Hence $\ell(\pi) \geq \text{inv}(\pi)$ [2 points].

On the other hand, we can find an expression $\pi = s_1 \cdots s_r$ with $r = \text{inv}(\pi)$ by sorting $\pi = \pi_1 \cdots \pi_n$ [3 points] because multiplying the simple transposition $(i, i+1)$ to the right of $\pi = \pi_1 \cdots \pi_n$ gives

$$\pi(i, i+1) = \pi_1 \cdots \pi_{i-1} \pi_{i+1} \pi_i \pi_{i+1} \cdots \pi_n.$$

This implies $\ell(\pi) \leq \text{inv}(\pi)$ [2 points]. Thus, $\ell(\pi) = \text{inv}(\pi)$. □

Problem 2.4. Prove that

$$\sum_{\pi \in \mathfrak{S}_n} q^{\text{inv}(\pi)} = (1+q)(1+q+q^2) \cdots (1+q+\cdots+q^{n-1}).$$

Solution. We proceed by induction on n . If $n = 1$, it is true. Let $n \geq 2$ and suppose the statement holds for $n-1$. Every $\pi \in \mathfrak{S}_n$ is obtained from $\sigma \in \mathfrak{S}_{n-1}$ by inserting n after j integers from the beginning for some $0 \leq j \leq n-1$ [3 points]. This construction gives $\text{inv}(\pi) = \text{inv}(\sigma) + j$

[3 points]. Thus

$$\begin{aligned} \sum_{\pi \in \mathfrak{S}_n} q^{\text{inv}(\pi)} &= \sum_{\sigma \in \mathfrak{S}_{n-1}} \sum_{j=0}^{n-1} q^{\text{inv}(\sigma)+j} = \sum_{\sigma \in \mathfrak{S}_{n-1}} q^{\text{inv}(\sigma)} (1 + q + \cdots + q^{n-1}) \quad [\mathbf{2 \ points}] \\ &= (1 + q)(1 + q + q^2) \cdots (1 + q + \cdots + q^{n-1}) \quad [\mathbf{2 \ points}]. \end{aligned}$$

Thus the statement is also true for n and we are done.

□

3. HOMEWORK 3 (DUE: OCT 19)

Problem 3.1. Suppose that $\{P_n(x)\}_{n \geq 0}$ is a monic OPS for a linear functional \mathcal{L} with $\mathcal{L}(1) = 1$ given by $P_{-1}(x) = 0$, $P_0(x) = 1$, and for $n \geq 0$,

$$P_{n+1}(x) = (x - n)P_n(x) - nP_{n-1}(x).$$

Compute the following.

- (1) $\mathcal{L}(x^3)$
- (2) $\mathcal{L}(P_{10}(x)P_{10}(x))$
- (3) $\mathcal{L}(x^3P_{10}(x)P_{12}(x))$

Solution. We can compute these quantities using

$$\mathcal{L}(x^n P_r(x) P_s) = \lambda_1 \cdots \lambda_s \sum_{\pi \in \text{Motz}((0,r) \rightarrow (n,s))} \text{wt}(\pi).$$

- (1) $\mathcal{L}(x^3) = 1$ [3 points]
- (2) $\mathcal{L}(P_{10}(x)P_{10}(x)) = 10!$ [3 points]
- (3) $\mathcal{L}(x^3P_{10}(x)P_{12}(x)) = 33 \cdot 12!$ [4 points]

□

Problem 3.2. A *left-to-right minimum* of a permutation $\pi = \pi_1 \cdots \pi_n$ is a number π_i such that $\pi_i = \min\{\pi_1, \dots, \pi_i\}$. Let $\text{LRmin}(\pi)$ denote the number of left-to-right minima in π . For example, if $\pi = 6741352$, then the left-to-right minima are 6, 4, 1, hence $\text{LRmin}(\pi) = 3$. Prove that

$$\sum_{\pi \in \mathfrak{S}_n} \alpha^{\text{cycle}(\pi)} = \sum_{\pi \in \mathfrak{S}_n} \alpha^{\text{LRmin}(\pi)}.$$

Solution. We can uniquely write the cycles of a permutation $\pi \in \mathfrak{S}_n$ so that each cycle starts with its smallest element and the cycles are listed in the decreasing order of their smallest elements [3 points]. For example,

$$\pi = (5, 11)(3)(1, 4, 2, 9, 10, 7, 6, 8).$$

Let $\hat{\pi}$ be the permutation obtained from this list of cycles by deleting the parentheses [4 points]. In the example above,

$$\hat{\pi} = 5 \ 11 \ 3 \ 1 \ 4 \ 2 \ 9 \ 10 \ 7 \ 6 \ 8.$$

Then the first elements of the cycles of π are the left-to-right minima of $\hat{\pi}$ [3 points]. Since $\pi \mapsto \hat{\pi}$ is a bijection we have

$$\sum_{\pi \in \mathfrak{S}_n} \alpha^{\text{cycle}(\pi)} = \sum_{\pi \in \mathfrak{S}_n} \alpha^{\text{LRmin}(\pi)}.$$

□

Problem 3.3. Suppose that $\{P_n(x)\}_{n \geq 0}$ is a monic OPS given by $P_{-1}(x) = 0$, $P_0(x) = 1$, and for $n \geq 0$,

$$P_{n+1}(x) = (x - 1)P_n(x) - nP_{n-1}(x).$$

Prove that μ_n is equal to the number of involutions in \mathfrak{S}_n . (An involution is a permutation π such that π^2 is the identity map.)

Solution. Recall the bijection $\phi : \text{CH}_n \rightarrow \Pi_n$ between the Charlier histories of length n and the set partitions of $[n]$ for the case $b_n = n + 1$ and $\lambda_n = n$ [3 points]. If $b_n = 1$ and $\lambda_n = n$, then by restricting this map to the Charlier histories with 0 label for every horizontal step, the images are the set partitions in which every block is of size 1 or 2 [4 points]. Then we can identify such a set partition as an involution [3 points]. This implies the statement in the problem. □

Problem 3.4. Suppose that $\{P_n(x)\}_{n \geq 0}$ is a monic OPS given by $P_{-1}(x) = 0$, $P_0(x) = 1$, and for $n \geq 0$,

$$P_{n+1}(x) = (x - b_n)P_n(x) - \lambda_n P_{n-1}(x),$$

where $\lambda_n \neq 0$ for all $n \geq 1$.

Using the fact $\mu_n = \sum_{\pi \in \text{Motz}_n} \text{wt}(\pi)$, prove that $\mu_{2n+1} = 0$ for all $n \geq 0$ if and only if $b_n = 0$ for all $n \geq 0$.

Solution. (\Leftarrow): Suppose $b_n = 0$ for all $n \geq 0$. Then μ_n is the generating function for Dyck paths, hence $\mu_{2n+1} = 0$ [**3 points**].

(\Rightarrow): Suppose that $\mu_{2n+1} = 0$ for all $n \geq 0$. Then we prove $b_n = 0$ for all $n \geq 0$ by induction on n . Since $\mu_1 = b_0$, we have $b_0 = 0$ [**3 points**]. Suppose that $b_i = 0$ for all $0 \leq i < n$. Then

$$\mu_{2n+1} = \sum_{\text{Motz}_{2n+1}} \text{wt}(\pi) = b_n \lambda_1 \cdots \lambda_n \quad [\mathbf{4 \text{ points}}]$$

because all Motzkin paths in Motz_{2n+1} except $U^n H D^n$ has weight 0. Since $\mu_{2n+1} = 0$ and $\lambda_i \leq 0$ for all i , we obtain $b_n = 0$. By induction, $b_n = 0$ for all $n \geq 0$. \square

4. HOMEWORK 4 (DUE:)

Definition 4.1. A *multiset* is a set of elements with multiplicities. We write $\{1^{a_1}, 2^{a_2}, \dots, n^{a_n}\}$ to mean a multiset with a_1 1's, a_2 2's, and so on.
